Paediatric Clostridium (Clostridioides) Difficile Infection – Treatment Guidelines

**Purpose**
This guideline provides recommendations regarding best practice for clinicians diagnosing and treating Clostridium Difficile Infection (CDI) in children.

**Scope**
This guideline provides information for all Children’s Health Queensland (CHQ) staff caring for children who have Clostridium Difficile Carriage and CDI.

Guideline

Background

C. difficile, a gram positive spore-forming anaerobic bacillus, is part of the normal bowel flora (3% in healthy adults, 16 to 35% in hospitalised patients). Asymptomatic carriage is common in young children (50 to 70% in infants) and thus detection of C. difficile in formed stools simply reflects carriage.

The development of C. difficile gastrointestinal infection results from the production of toxins (Toxins A and B) by overgrown C. difficile in a susceptible host. The causes are multifactorial, including altered bowel flora due to antibiotic use, gastric acid suppression, gastrostomy / jejunostomy feeding tubes, immunodeficiency, malignancy, transplantation, and possibly inflammatory bowel disease. Symptoms range from mild to severe diarrhoea, pseudomembranous colitis to toxic megacolon and fatal colonic perforation.

Clinical illness is rarely reported before 12 to 24 months of age. It is possible that neonates / infants may lack the cellular machinery to bind and process the toxins of Clostridium species.

In the setting of a high prevalence of asymptomatic carriage, detection of C. difficile toxin cannot be assumed to be the causative agent for diarrhoea in children before adolescence, particularly children under 3 years of age. This creates challenges in defining infection and deciding whether treatment is required in children.

Definition

C. difficile infection (CDI):

Three or more diarrhoeal stools in 24 hours; defined as stools loose enough to take the shape of a container used to sample it, not attributable to any other cause, including medicines

AND

microbiological evidence of toxin-producing C. difficile (positive toxin A / B assay)

OR

endoscopic evidence of pseudomembranous colitis (PMC).

In suspected cases of ‘silent’ CDI, such as ileus, toxic megacolon or pseudomembranous colitis without diarrhoea, other diagnostic procedures, such as colonoscopy, white blood cell (WBC) count, serum creatinine and abdominal CT scanning, may be required.

More than one test per patient may be required if the first test is negative and there is a strong clinical suspicion of CDI. Retest a second sample 24 hours later. Further tests might be necessary in light of additional clinical evidence.

ALERT

Because of the high prevalence of asymptomatic carriage of toxigenic C. difficile in infants, testing for CDI should never be routinely recommended for neonates or infants less or equal to 12 months of age with diarrhoea.

Antimicrobial therapy is not indicated in children with asymptomatic colonization with C. difficile.
Severity assessment:

<table>

Score Disease severity

- 1 to 2 Mild
- 3 to 4 Moderate
- 5 or more Severe

Severe CDI:
Unusual in children, however any of the following features are suggestive:

- **Clinical**
  - Fever (more than 38.5 °C), rigors.
  - Haemodynamic instability.
  - Peritonitis or evidence of bowel perforation.
  - Ileus or toxic megacolon.

- **Laboratory**
  - WBC count more than 15 x 10^9 / L and less than 20% neutrophils.
  - Elevated lactate level.
  - Rise in creatinine level (more than 50% above baseline).
  - Albumin level less than 25 g/L.
- **Other investigations**
  - Radiographic features of large bowel distension, bowel wall thickening, fat stranding, and/or unexplained ascites.
  - Pseudomembranous colitis (colonoscopy).

**Life-threatening CDI** includes hypotension, partial or complete ileus or toxic megacolon, or Computed tomography (CT) evidence of severe disease such as perforation.

**Treatment of CDI**

**General measures**
Assess hydration and manage appropriately (refer to [CHQ-GDL-01025 Intravenous Fluid Guidelines – Paediatric and Neonatal](#)).

Ongoing clinical (fevers / abdominal pain / bowel chart) and biochemical assessment (full blood count, lactate, electrolytes) required.

Avoid and/or stop all non-essential antibiotic therapy inhibitors where possible / clinically indicated.

Promote the use of narrow spectrum antimicrobial agents.

Stop therapy with other antibiotics if possible; if not, a prolonged course of treatment for CDI may be required.

Avoid and/or stop all anti-motility agents, opiates and proton pump inhibitors where possible / clinically indicated.

Perform serial clinical assessments and assess severity.

**Treatment: Mild CDI** (score 1 to 2)

- No need to treat if symptoms settle within 24 hours and diarrhoea frequency or consistency decreases.

- **Metronidazole oral** (10 mg/kg/dose three times a day; maximum 400 mg/dose) for 10 to 14 days.

**Treatment: Moderate CDI** (score 3 to 4)

- **Metronidazole oral** (10 mg/kg/dose three times a day; maximum 400 mg/dose) for 10 days.

- For patients who fail to respond to initial therapy after 3 days, switching to oral vancomycin should be considered. **Vancomycin oral** (10 mg/kg/dose four times a day; maximum 125 mg/dose) for 10 to 14 days.

**Treatment: Severe CDI** (score 5 or more)

- **Vancomycin oral** (10 mg/kg/dose every 6 hourly; maximum 500 mg/dose) for 10 days. (Vancomycin serum trough levels should be monitored if maximum dose of 40 mg/kg/day; up to maximum 2 g/day orally is given).

- In severe or complicated CDI cases **not** responding to oral vancomycin, **add intravenous metronidazole** (10 mg/kg/dose every 8 hourly; maximum 500 mg/dose). Medication administration information can be
found in the Paediatric Injectable Guidelines, or SHPA Australian Injectable Drugs Handbook available online via the Clinicians Knowledge Network.

- Such patients should be closely monitored, with specialist surgical input:
  - Measure blood lactate.
  - Colectomy should be considered, especially if caecal dilatation is more than 10 cm.
  - Colectomy is best performed before blood lactate rises above 5 mmol/L, when survival is extremely poor.

**Response to treatment**

The response to treatment of *C. difficile* disease is monitored clinically. In patients with mild to moderate disease, fever, systemic manifestations, and frequency of diarrhoea generally improve within 24 to 48 hours of initiating antibiotic therapy, but diarrhoea may not fully resolve for 4 to 5 days.

If diarrhoea persists despite 20 days treatment but the child is stable and the daily number of diarrhoeal stools has decreased, the WBC is normal, and there is no abdominal pain or distension, the persistent diarrhoea may be due to post-infective irritable bowel syndrome.

The child may be treated with an anti-motility agent such as loperamide (Dose: 0.1 to 0.2 mg/kg/dose up to three to four times a day. Maximum 2 mg/dose, maximum 8 mg/day) (instead of metronidazole or vancomycin).

The patient should be closely observed for evidence of a therapeutic response and to ensure there is no evidence of colonic dilatation.

Follow-up faecal toxin assays are not recommended because patients often remain colonized with toxin-producing strains after recovery.

Patients remain vulnerable to relapse or reinfection for up to 10 weeks following treatment for *C. difficile* infection.

**First recurrence CDI: (relapse or re-infection)**

Increasing stool frequency over 2 consecutive days for which no alternative cause is identified.

OR

New signs of severe CDI after apparent improvement

---

**ALERT**

Re-testing of patients for *C. difficile* toxins is generally not helpful as colonisation may persist for some weeks.
Treatment first recurrence
Conservative treatment may be appropriate in mild disease.
If antibiotics are needed, repeat the same antibiotic used to treat the initial episode.
Unless the first episode was treated with metronidazole and the recurrence is severe CDI, in which case vancomycin should be used.

For subsequent recurrences: (discuss with Paediatric Infectious Diseases)

Vancomycin in a pulsed / tapering course: \(^8, 14\)

Vancomycin
10 mg/kg/dose (maximum 125 mg/dose) orally, four times daily for 14 days,
then
10 mg/kg/dose (maximum 125 mg/dose) orally twice daily for 7 days,
then
10 mg/kg/dose (maximum 125 mg/dose) orally once daily for 7 days,
then
10 mg/kg/dose (maximum 125 mg/dose) orally every 48 hours for 7 days,
then
10 mg/kg/dose (maximum 125 mg/dose) orally every 72 hours for 14 days.

The use of intermittent antibiotic therapy is based upon a theory that relapse may be due to the presence of persistent spores that survive antibiotic therapy. Intermittent therapy may allow the spores to germinate on the days when no antibiotics are administered. Once the spores have converted to the fully functional vegetative, toxin-producing forms, they are susceptible to killing when the antibiotics are readministered.

Refractory disease after a tapered / pulsed oral vancomycin course: (discuss with Paediatric Infectious Diseases)

Vancomycin orally for 2 weeks for refractory disease: \(^{13}\)
Vancomycin oral:
10 mg/kg/dose (maximum 500 mg/dose) orally, four times daily for 14 days,
Followed by Nitazoxanide** orally for 2 weeks
Nitazoxanide oral:
- 1 to 3 years of age: 100 mg/dose orally twice daily for 3 days.
- 4 to 11 years of age: 200 mg/dose orally twice daily for 3 days.
- 12 years and older: 500 mg/dose orally twice daily for 3 days.
Other antimicrobial agents with activity against *C. difficile* include rifaximin**, and fidaxomicin (FDA approved for treatment of CDI in adults); criteria for optimal use of these drugs in children are unknown and there are concerns around rifaximin and the rapid induction of antimicrobial resistance.

**Note:** Nitazoxanide and Rifaximin are not commercially available in Australia (only available via Special Access Scheme (SAS) and on approval of Paediatric Infectious Diseases specialist).

**Fidaxomicin (discuss with Paediatric Infectious Diseases)**

Fidaxomicin is a macrocyclic antibiotic that is approved for the treatment of *C. difficile* infection in persons 18 years of age and above. In randomized trials in adults, the efficacy of fidaxomicin was similar to vancomycin, but the risk of relapse was reduced. A preliminary study in children suggests that it is safe with little gastrointestinal absorption. A randomized trial comparing fidaxomicin and oral vancomycin in children with *C. difficile* infection is underway.

- 1 month to 5 years of age: 16 mg/kg/dose orally twice daily for 10 days (maximum 200 mg/dose).
- 5 years of age and older: 200 mg/dose orally twice daily for 10 days.

---

**Alert**

Oral vancomycin, nitazoxanide and fidaxomicin are restricted antibiotics and require Infectious Diseases (ID) team approval.

---

**Alternative treatments: (discuss with Paediatric Infectious Diseases)**

**Probiotics**

Probiotics, specifically *Saccharomyces boulardii*, may be a useful adjunct to antibiotics in non severe *C. difficile* infection, however cases of invasive disease associated with the use of probiotics have been described. No published expert policy statements recommend the use of probiotics for either the prevention or the treatment of CDI, as the evidence is inconclusive especially in children.

Probiotics should not be used routinely or in the immunocompromised.

**Passive immunotherapy**

Anecdotal reports suggest possible improvement with Intravenous Immunoglobulin (IVIG) 400 mg/kg every three weeks. Use of IVIG is not recommended, though may be supported in life threatening disease.

**Faecal Transplant (FMT)**

Faecal transplantation (enteric administration of donor stool flora) is highly effective for severe, intractable infection in adults. Faecal microbiota transplants can be considered in children in consultation with Gastroenterology and Infectious Diseases.
